Conclusion:

BoW Model Performance

- On **Dataset 1**, the original BoW model (bow 1) achieved **80.12%** accuracy.
- On **Dataset 2**, bow_1 performed at **76.33%**, but after fine-tuning (bow_2), it improved significantly to **88.26%**. This highlights that adapting the model to the IMDB dataset allowed it to generalize better to its specific language patterns, improving test accuracy.

BERT Embedding Model Performance

- On **Dataset 1**, the BERT-based model (bert_1) had a strong baseline performance of **86.55%**, outperforming BoW.
- On **Dataset 2**, bert_1 started with **81.19%** accuracy, but after fine-tuning (bert_2), it improved to **88.9%**, indicating that additional training on the IMDB dataset helped the model adapt better to its specific linguistic patterns and sentiment structures.

Fine-tuning significantly boosts a model's performance on a target dataset, as seen in bow_2 and bert_2 on Dataset 2. However, this often comes at the cost of slight performance degradation on the original dataset, highlighting a trade-off between generalization and dataset specialization.

- **BoW has more features but lacks context and sentence structure.** It relies on word frequency, making it limited in capturing deeper meaning.
- BERT embeddings, despite having fewer dimensions, capture more meaningful relationships between words and sentences due to their deep contextual understanding.

This explains why BERT-based models (bert_1 and bert_2) achieved **higher baseline** accuracy than BoW, as they leveraged better feature representations rather than just raw word counts.
